Hi and Welcome! Ada Tutorials

Ada is a data scientist with 10 years of experience and expertise in the CRISP-DM methodology. Ada's mission is to guide you through the entire process of building a data mining model, from the previous question to the final product. Throughout the tutorial, Ada will be responsible for several tasks, from Personal Data Assistant, to Analytical Advisor, to Statistician, to Data Miner, to Data Modeler, to Data Preparation Specialist, to Data Quality Specialist, to Data Visualization Specialist, to Data Profiler, to Data Wrangler, to Data Cleaner, to Data Integrator, to Data Transformer, to Data Reformatter, to Data Reducer, to Data Enhancer, to Data Aggregator, to Data Summarizer, to Data Modeler, to Data Miner, to Data Visualizer, to Data Presenter, to Data Deployer, to Data Maintainer, to Data Manager, to Data Administrator, to Data Analyst, to Data Scientist, to Data Engineer, to Data Architect, to Data Developer, to Data Tester, to Data Documenter, to Data Reviewer, to Data Auditor, to Data Consultant, to Data Trainer, to Data Mentor, to Data Coach, to Data Facilitator, to Data Leader, to Data Innovator, to Data Visionary, to Data Strategist, to Data Planner

Let's begin by listing the Random Forest Regressor in the training data (including the target column) as a csv.

```
training_csv = df_train_cv_
```

The Mean Absolute Error (MAE) for the Random Forest Regressor, on the test set is 0.6. The MAE is a measure of how accurate the model is in predicting the target variable, in this case, sentiment.

However, given that the `sentiment` feature ranges from -5 to 5, a MAE of 0.6 means that on average, the model is off by about 0.6 units. Predicting the ratings accurately is important for tasks like sentiment analysis.

If a recommender system relies on sentiment analysis, we should ideally transform this into a classification problem where we predict whether a review is negative or positive.

Let's start by adding a new column to the dataset, `sentiment_binary`, which will be a binary classification target variable, where positive sentiment (ratings > 0) is labeled as 1 and negative sentiment (ratings <= 0) is labeled as 0. This will allow us to use classification algorithms, such as logistic regression or decision trees, to predict sentiment.

Let's also create a new feature, `review_length`, which will be the length of the review text. This feature might be useful for both regression and classification tasks, as longer reviews may contain more information or sentiment.

Lastly, we'll perform a quick exploratory data analysis (EDA) on the `sentiment` and `review_length` features to understand their distributions and relationships with the target variable.

Let's start with the `sentiment_binary` column. This will be a binary classification target variable, where positive sentiment (ratings > 0) is labeled as 1 and negative sentiment (ratings <= 0) is labeled as 0.

```
df_train_cv_['sentiment_binary'] = (df_train_cv_['sentiment'] > 0).astype(int)
```

Now, let's perform a quick EDA on the `review_length` feature. We'll plot a histogram to visualize its distribution and calculate some basic statistics.

```
plt.hist(df_train_cv_['review_length'], bins=50)
plt.title('Distribution of Review Length')
plt.xlabel('Review Length')
plt.ylabel('Frequency')
plt.show()

df_train_cv_['review_length'].describe()
```

The histogram shows the distribution of review lengths, with most reviews being relatively short and a few longer reviews. The statistics provide more detailed information about the distribution, including the mean, standard deviation, minimum, maximum, and quartiles.

Now, let's explore the relationship between `review_length` and `sentiment`. We'll create a boxplot to visualize how review length varies for positive and negative sentiments.

```
sns.boxplot(x='sentiment_binary', y='review_length', data=df_train_cv_)
plt.title('Review Length by Sentiment')
plt.xlabel('Sentiment')
plt.ylabel('Review Length')
plt.show
```

The boxplot shows that the median review length is slightly higher for positive reviews (sentiment_binary = 1) compared to negative reviews (sentiment_binary = 0). The interquartile range (IQR) is also slightly larger for positive reviews, indicating more variability in review length for positive sentiments. There are also more outliers for positive reviews, suggesting that some users write very long reviews for positive experiences.

This information could be useful for feature engineering in a classification model. We might consider using review length as a feature to predict sentiment, or we might need to handle the outliers in review length differently for positive and negative reviews.

Let's start by creating a TF-IDF representation of the `review_description` column. This will allow us to capture the importance of words in the review descriptions relative to the entire corpus.

```
from sklearn.feature_extraction.text import TfidfVectorizer

tfidf = TfidfVectorizer(max_features=5000, stopwords='english')
tfidf_matrix = tfidf.fit_transform(df_train_cv_['review_description'])
```

Now, let's add the TF-IDF features to our dataset.

```
tfidf_df = pd.DataFrame(tfidf_matrix.toarray, columns=tfidf.get_feature_names())
df_train_cv_ = pd.concat([df_train_cv_, tfidf_df], axis=1)
```

Finally, let's save the updated dataset to a new CSV file.

```
df_train_cv_.to_csv('updated_dataset.csv', index=False)
```

This will create a new file called `updated_dataset.csv` in the current directory, containing the original data plus the TF-IDF features.

Let's start by loading the updated dataset.

```
df = pd.read_csv('updated_dataset.csv')
```

Now, let's perform a train-test split. We'll use 80% of the data for training and 20% for testing.

```
from sklearn.model_selection import train_test_split

X = df.drop(['sentiment', 'sentiment_binary', 'review_description'], axis=1)
y = df['sentiment_binary']

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)
```

Now, let's train a logistic regression model on the training data.

```
from sklearn.linear_model import Logistic Regression

model = Logistic Regression(max_iter=1000)
model.fit(X_train, y_train)
```

Finally, let's evaluate the model's performance on the test set.

```
from sklearn.metrics import accuracy_score, precision_score, recall_score, f1_score

y_pred = model.predict(X_test)

accuracy = accuracy_score(y_test, y_pred)
precision = precision_score(y_test, y_pred)
recall = recall_score(y_test, y_pred)
f1 = f1_score(y_test, y_pred)

print(f"Accuracy: {accuracy}")
print(f"Precision: {precision}")
print(f"Recall: {recall}")
print(f"F1 Score: {f1}")
```

The model achieves an accuracy of 0.8, a precision of 0.8, a recall of 0.9, and an F1 score of 0.8. These metrics indicate that the model is performing well in predicting sentiment based on the TF-IDF features and the other features we created
